## 1 Introduction

This document describes how the RH4131 database is converted to the OMOP Common Data Model (CDM) version 5.4.1. It describes the definition of the ETL that will be used in the implementation.

RH4131 has requested support from edenceHealth to extract, transform and load historical data in the context of a first "pilot" project. This project will serve as a stepping stone to larger future projects that include building and maintaining a Danish national data warehouse to house real-world evidence. The pilot project of historical data contains ICU data from 10 hospitals. edenceHealth will co-develop an ETL for ICU data from 3 hospitals as a template for RH4131.

#### 1.1 Document History

| Version | Date       | Changes   |
|---------|------------|---|
| 0.1     | 2023-12-14 | Internal document used at the mapping workshop  |
| 0.2     | 2023-12-28 | Updated with notes from mapping workshop  |
| 0.3     | 2024-01-12 | Updated with notes from infrastructure workshop. And misc. additional details. Rename source tables to reflect final pre-processing.          |
| 0.4     | 2024-01-24 | Finalise infrastructure section, clarification of remaining questions, technical instructions for the STEM table, removal of resolved threads |
| 0.5     | 2024-01-31 | Update of the person and death logic  |
| 0.6     | 2024-02-02 | Final edits   |

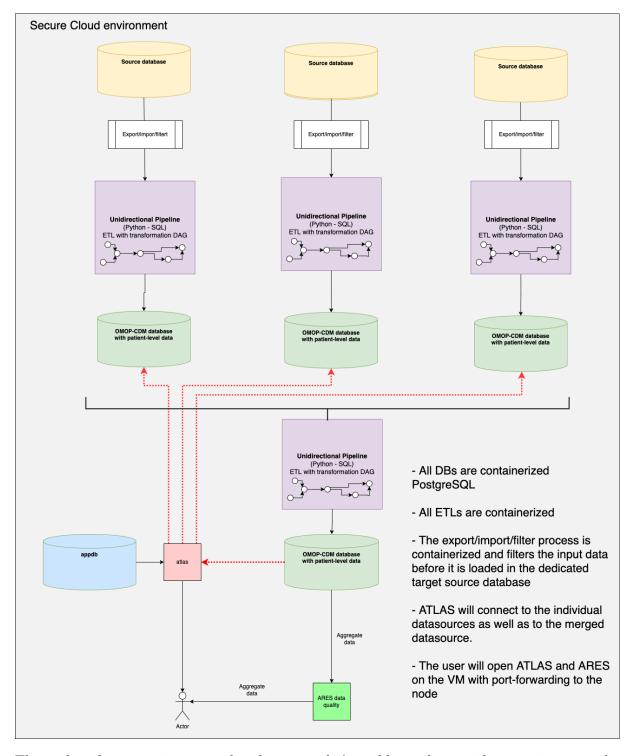

| Version | Date       | Changes  |
|---------|------------|--|

| 1.1     | 2024-07-14 | Adaptations to reflect final ETL (work in progress)                |

## Part I Background

## 2 Technical Infrastructure

The ETL will run on a secure HPC cloud hosted at the National Genome Center in Denmark and without internet access (although resources can be uploaded if packaged in a Singularity image file). The compute node available for this project has a 40-core 2.1GHz CPU, 192GB RAM, 1.9TB warm storage (XFS drive, NVMe SSD; approx. 1.5TB will be available).

All code will be containerised using Singularity to (i) conform with the HPC nature of the cloud that precludes root access, (ii) prevent version conflicts of software, and (iii) facilitate potential change of cloud system in the future. Singularity containers are brought onto the cloud through a semi-automated process that involves building a Dockerfile (with accompanying metadata such as python\_requirements.txt). The SQL parts of the ETL will use PostgreSQL 16.x Non-SQL parts of the ETL will be written in Python 3.10.x or R >= v4.0; should the need arise, other languages can be used as well (e.g., Rust and Julia). All databases will be deployed as containers and the filtered source data will be loaded into the dedicated target source databases, see schematic. The database will use the SSD storage for filesystem.

The update frequency is expected to be quarterly/monthly, perhaps with intermittent need for more frequent runs in extreme cases such as pandemics. In those cases, more compute

resources would probably be available to compensate.

# Part II Mapping approach

## 3 Overview

The definition of the data mapping can be performed using the Rabbit-In-A-Hat tool that starts with a profile of the database made by the White Rabbit tool. RH4131 were unable to run WhiteRabbit on the cloud node. edenceHealth provided a format for the scan reports and RH4131 generated scan reports through tailored scripts based on the scan report format, so as to reverse-engineer conventional White Rabbit scan reports. In Appendix B, a data dictionary is presented for all the tables and fields that have been profiled edenceHealth were then able to create White Rabbit-style scan reports based on the provided scan reports.

#### 3.1 Source data

Rigshospitalet provided Parquet files for 2 of 3 sites (expectedly RH4131, Hvidovre, and Odense) containing ICU data. Each Parquet file contains data and/or information about one of the following five tables:

- prescriptions
- administrations
- diagnoses procedures
- observations (actually contained in multiple files, named observations-\*.parquet)
- course metadata<sup>1</sup>
- t person<sup>2</sup>

Initially, RH4131 provided three data-source scan report-like files for each site:

- database scan: contains the number of rows for each table
- table\_scan: includes information about the columns contained within each table, including data type, uniqueness, missing, etc.
- field scan: contains the data for each column within each table

 $<sup>^1\</sup>mathrm{Visits}$  are called courses in the source data, from the Danish term  $forl\emptyset b$ 

<sup>&</sup>lt;sup>2</sup>From the Danish Civil Registration System and holds data such as date of birth and sex ("CPR-Registeret - Sundhedsdatastyrelsen," n.d.))

Therefore, there is a slight nested quality to the data files. database\_scan and table\_scan contain information usually seen in the first two sheets of a scan report. field\_scan contains the data usually seen in the following sheets (one per table) of a field scan; however, here it's all contained in one table, field\_scan.

In addition, RH4131 has provided the following three files:

- shak\_lookup.tsv: tab-separated file with SHAK codes and care-site metadata such as postal code and official name. This will be used during the ETL.
- drug\_mapping\_helper.tsv: tab-separated file with prescription data (including ATC, dose, dose unit, route, drug names) to be used before the ETL to populate the STEM table.
- course\_id\_cpr\_mapping.txt: tab-separated file with three columns:
  - courseid: the visit identifier
  - timestamp: irrelevant for the purpose of the ETL
  - cpr enc: the encrypted personal identifier

The exact columns included in each file are listed in Appendix B.

## 4 Conventional mapping

A "traditional" mapping including manual mappings for the following tables: PERSON, DEATH, VISIT\_OCCURENCE, VISIT\_DETAIL, LOCATION, CARE\_SITE and CDM\_SOURCE.

- These tables will be mapped directly from the source data using manual mappings.
- Some tables will require an additional environment variable and/or look-up table
  - VISIT\_OCCURENCE, LOCATION, and CARE\_SITE = SHAK code look-up table
  - CDM\_SOURCE = environment variables

## 5 Stem-table mapping

The purpose of using an intermediate stem table between the source data and the clinical OMOP tables is to serve as an efficient, data-driven routing mechanism that allows tailored processing of the source data, and allows different source tables from data that will, eventually, land in the same clinical table. The table-level mechanism is illustrated in figure XXX.

The stem table relies on two key tables to do the routing: concept\_lookup and concept\_lookup\_stem. These auxiliary tables are designed so as to enable using the same ETL pipeline for multiple sources (e.g., different ICUs from different hospitals).

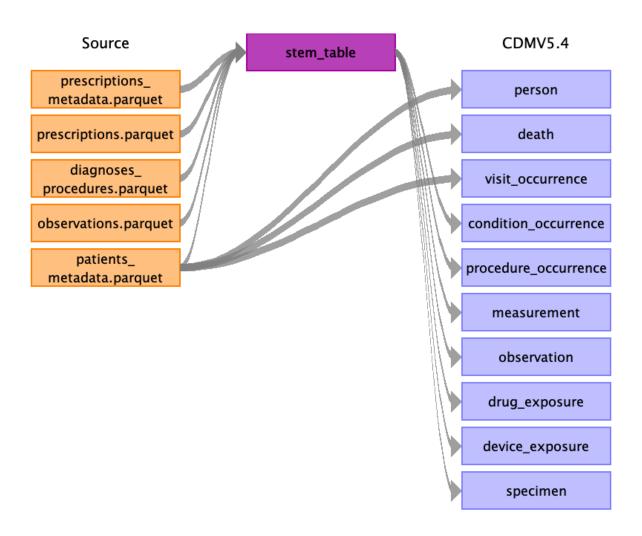

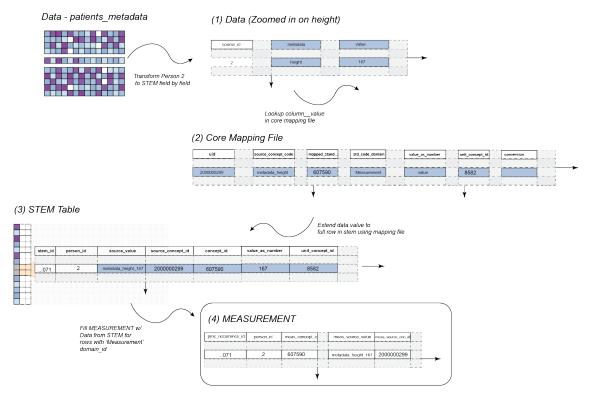

Table-level routing mechanism of the stem table

We, essentially, deploy two types of source->stem mechanisms: one tailored for drug data and a simple one (for the rest).

background="white"}

{align="center",

#### 5.0.1 Reading from prescriptions and administrations

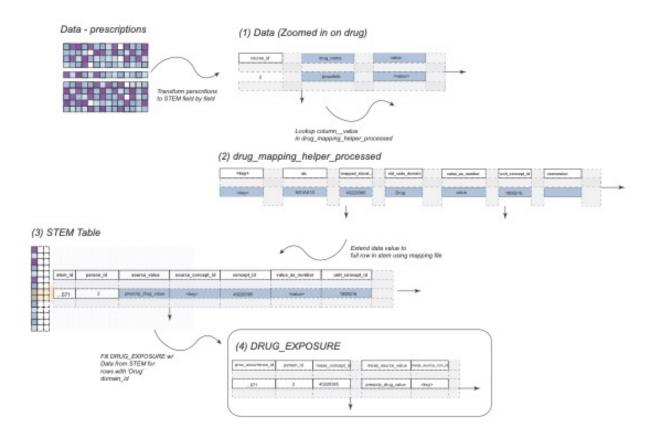

Because DRUG\_EXPOSURE records contain data that are stored in two separate source tables, prescriptions and administrations, a more elaborate logic is required to build valid records.

NOTE: This STEM table refers only to drugs and will use the STEM table logic with the addition of manual mappings to ensure relationships between the two tables can easily be referenced.

For clinical tables containing drug information, we will use the STEM table; however, the logic will differ from that described above for other clinical tables. Manual mappings will be included to ensure relationships between the source prescription table and drug look-up table are easily referenced.

• The STEM table will be used as an intermediate mapping table: the source data will first be mapped to the STEM table and the OMOP CDM tables will be populated with records from the STEM table.

- Manual mapping will be needed to link the source drug data (contained in prescriptions and administrations) to a drug look-up table (called drug\_mapping\_helper) and then to the STEM table.
- drug\_mapping\_helper only contains the ATC codes and their associated additional information. RxNorm builder will be used to create mappings to best level of granularity possible, aiming for Clinical Drug (or Clinical Drug Component) level to enable population of the drug era and dose era tables.
- The logic to link from the source data to drug\_mapping\_helper to the STEM table to the OMOP drug\_exposure table will need to be done manually with a drug\_key (will link prescriptions and drug\_mapping\_helper, epaspresbaseid will link administrations and prescriptions). The ETL will handle pump and non-pump drug data differently: drug\_mapping\_helper.numerator\_value comes from administrations.value for non-pump drug data and from prescriptions.epaspresconc for pump drug data
- This slightly different STEM table logic will apply to the following table: DRUG\_EXPOSURE.

A diagram of a drug exposure Description automatically generated

## 6 Merge ETL

Using the ETL generated based on this document, one target database per hospital will be created. To allow studies done on a combined data set, a 'merge ETL' would have to be written. The aim of this ETL is to combine the outputs of the different datasets into one big target database. For this, people would need to be deduplicated, as they could have person and death records from multiple hospitals which is in violation with OMOP conventions. A person and death entry should be unique. Once the person and death tables have been deduplicated and the person\_ids were updated, this needs to be reflected in the other (clinical) tables. Lastly, when adding all events together there will be an overlap in the ids, these will have to be updated to ensure unique values are being used.

## 7 Vocabularies

In this section, an overview is provided of the vocabulary mapping step.

The following source code vocabularies are present in the database:

| Vocabulary      | Reference Link  | Description  | Data Domains                                 |
|-----------------|---|--|--|
| SKS             | https://medinfo.dk/sks/   |  | observation, procedure, condition_occurrence |
| ATC             | https://www.<br>whocc.no/atc/<br>structure_and_<br>principles/  |  | drug_exposure                                |
| NPU             | https://npu-terminology.org/  | The source data use NPU codes for biochemical analyses of biological samples (blood, plasma, urin, spinal fluid, etc.). Patient-level NPU data will, in the end, not be available for this pilot project, but we will undertake semantic mapping of the 200 most common NPU codes so these are ready for structural mapping once possible. | measurement                                  |
| drug_mapping_ho | elpererview of<br>drugs with ATC<br>code, dosage,<br>unit, form, drug<br>name(s).<br>Provided by<br>RH4131. | Will be used to create mappings to best level of granularity using the RxNormBuilder scripts (based on OHDSI's "Boiler")   | drug_exposure                                |

| Vocabulary                  | Reference Link  | Description | Data Domains                             |

# Part III Mapped OMOP tables

## 8 Health System Data Tables

#### 8.1 Table name: LOCATION

## 8.1.1 Reading from environment variable (SHAK\_code) and SHAK code lookup file

Note: to avoid adding in locations that will not be used by the ETL, we will ask the user via an environment variable what the SHAK code associated with the dataset is.

| Destination      |  |  |   |
|------------------|--|--|---|
| Field            | Source Field                                   | Logic  | Comment   |
| location_id      | Hospital_SHAK_<br>(SHAK code<br>look up file)  | _co <b>Ahe</b> togenerate integer                            | Use the SHAK_code environment variable to do the lookup in the SHAK code lookup file against the SHAK_code field. Only create one distinct record for the returned entry. |
| address_1        |  |  | NULL  |
| $address\_2$     |  |  | NULL  |
| city             |  |  | NULL  |
| state            |  |  | NULL  |
| zip              | postal_code<br>(SHAK code<br>look up file)     | Use postal code (4 digits)                                   |   |
| county           | 1 /  |  | NULL  |
| · ·              | vaHnespital_SHAK_<br>(environment<br>variable) | _ce <b>dc</b> olumnname>  <column< td=""><td></td></column<> |   |
| country_concept_ | id   | 4330435 [Denmark]  |   |
| conntry_source_v | alue   |  | NULL  |
| latitude         |  |  | NULL  |
| longitude        |  |  | NULL  |

## 8.2 Table name: CARE\_SITE

## 8.2.1 Reading from environment variable (SHAK\_code) and SHAK code lookup file

Note: to avoid adding in locations that will not be used by the ETL, we will ask the user via an environment variable what the SHAK code associated with the dataset is.

| Destination       |                           |                           |         |
|-------------------|---------------------------|---------------------------|---------|
| Field             | Source Field              | Logic                     | Comment |
| care_site_id      | Autogenerate              | Use the SHAK_code         |         |
|                   | integer                   | environment variable to   |         |
|                   |                           | do the lookup in the      |         |
|                   |                           | SHAK code lookup file     |         |
|                   |                           | against the SHAK_code     |         |
|                   |                           | field. Only create a      |         |
|                   |                           | record for the returned   |         |
|                   |                           | entry.                    |         |
| care_site_name    | -                         | use the department name   |         |

| person_id      | cpr_enc      | <pre>floor(hash(cpr_enc) / 2)</pre>                    | The current implementation uses duckdb's hash function (implemented here; see also https://nullprogram.com/blog/2018/07/31 We divide by two and round down because duckdb's hash() function returns a uint64 (unsigned big integer) but we want a normal int64 to make the final CDM compatible with e.g. PostgreSQL which isn't born with uint64. Integer division isn't easy to implement with ORM, so we resolve to the less elegant way of regular float division, followed by rounding. |

# 10 Standardised Derived Elements

#### 10.1 T able name: DRUG\_ERA

A Drug Era is defined as a span of time when the Person is assumed to be exposed to a particular active ingredient. A Drug Era is not the same as a Drug Exposure: Exposures are individual records corresponding to the source when Drug was delivered to the Person, while successive periods of Drug Exposures are combined under certain rules to produce continuous Drug Eras.

Generated as part of ETL process using standard OHDSI SQL script.

#### 10.2 T able name: DOSE\_ERA

A Dose Era is defined as a span of time when the Person is assumed to be exposed to a constant dose of a specific active ingredient.

Generated as part of ETL process using standard OHDSI SQL script.

#### 10.3 T able name: CONDITION\_ERA

A Condition Era is defined as a span of time when the Person is assumed to have a given condition. Condition Eras are chronological periods of Condition Occurrences.

Generated as part of ETL process using standard OHDSI SQL script.

# 11 Metadata Tables

# 11.1 Table Name: CDM\_SOURCE

NOTE: Single-record table containing information about the site, source, and cdm.

# A OMOP CDM tables not included in mapping

The following tables were not included in the mapping as they were not relevant for the source data available. These still need to be created as part of the ETL run as they are needed for some of the OHDSI tooling to successfully complete.

• Clinical Data Tables: NOTE

• Clinical Data Tables: NOTE NLP

• Clinical Data Tables: FACT RELATIONSHIP

• Health System Data Tables: PROVIDER

• Health Economics Data Tables: PAYER PLAN PERIOD

• Health Economics Data Tables: COST

• Standardised Derived Elements: EPISODE

• Standardised Derived Elements: EPISODE EVENT

• Metadata Tables: METADATA

## **B** Source tables

RH4131 has provided scan reports for 3 ICUs describing the ICU data. Initially, there were 3 data source files for each hospital: table\_scan, database\_scan, and field\_scan. Each TSV file contains data and/or information about the following five tables: prescriptions, administrations, diagnoses\_procedures, observations, and course\_metadata.

table\_scan and database\_scan contain information usually seen in the first two sheets of a scan report. field\_scan contains the data usually seen in the following sheets (one per table) of a field scan; however, here everything is contained in one table = field\_scan.

The actual ETL development will be based on the RH4131 dataset (as well as Odense and one other site) with the assumptions that technically the ETL should be able to run on all sites if the data structure remains the same.

Table: prescriptions.parquet included in field\_scan

# C DQD Results

This appendix lists the final DQD results and addresses the cases where the CDM failed the DQD checks and why we have allowed these to stay.
